

Electric hand tool

The invention relates to a manually operated apparatus or tool such as, for example, a drilling or holing apparatus, of the power hammer type, or a fastening
5 apparatus of the sealing apparatus type having a piston propelled by gas.

Such apparatuses may have operating and control electronics, an igniter plug, a fan, an electric motor
10 or other components requiring an electrical power supply. Being manually operated and self-contained, they also comprise a power supply battery.

Once the battery has been mounted on the outside of the
15 collection of the other elements of the apparatus, with the disadvantage, in particular, of exposing them to knocks which may damage them, a proposal was made to arrange them in an accommodating housing inside the
apparatus, formed, for example, in a leg connected to
20 the central body of the apparatus and running parallel to its operating handle.

As a safety measure, it was then proposed for the battery to be fixed in the apparatus by means of a
25 double-action locking device, it being possible first of all for the battery to be locked mechanically and electrically and then disconnected electrically from the remainder of the apparatus while remaining
mechanically connected thereto so as to prevent the
30 operator from letting it fall out through not paying sufficient attention. Document EP 1 205 282 teaches such a device comprising, on the apparatus, a double trigger for actuating two retaining fingers designed to
collaborate in succession with a single retaining catch
35 formed on the battery. However, such an arrangement does not set aside the risk of the operator inadvertently actuating the double trigger twice and thus completely releasing the battery from the

apparatus.

The present invention is aimed at reducing such a risk.

5 To this end, the invention relates first of all to an electric hand tool comprising, in a casing, electrically operated components and a housing to accommodate a battery that powers the said components, with detachable means of securing the battery in its
10 housing in a position of mechanical locking and electrical connection to the said components and in a position in which it is mechanically retained in its housing but electrically disconnected, characterized in that the securing means are designed to retain the
15 battery in the electrically disconnected position only by friction.

By virtue of the invention, in order to completely release the battery from the tool, an operator is
20 obliged to take it in his hand and remove it from its housing, overcoming the friction forces which retain it, thus avoiding any risk of an unintentional wrong move.

25 In the preferred embodiment of the tool of the invention, the battery-accommodating housing is designed to accommodate therein a battery by sliding, and the battery securing means comprise an electrical locking finger and a mechanical retaining finger both
30 mounted so that they can move, in a direction roughly orthogonal to the direction in which the battery slides, between a lock and a retaining position, respectively, and a retracted position.

35 As a preference, the locking and retaining fingers are mounted so that they can be moved into the retracted position against the action of elastic return means.

Advantageously, the locking finger is secured to a rod

mounted to slide into the retracted position against the action of a return spring under the action of an actuating trigger and the retaining finger is secured to a pivoting elastic leaf.

5

Advantageously too, the locking finger and the retaining finger are mounted to be moved into the retracted position, one in each of two opposite directions.

10

The invention also relates to a battery for powering electrically operated components for the electric hand tool of the invention, characterized in that it comprises a mechanical and electrical locking catch and

15

mechanical retaining ramp means.

In the preferred embodiment of the battery, the locking catch is formed by an undercut internal shoulder and the ramp means comprise a retaining boss with an entry
20 ramp and an opposite retaining ramp advantageously formed near the entry end of the battery, via which end it is introduced into its accommodating housing in the tool, the locking catch and the retaining boss being formed respectively on two opposite sides of the
25 battery.

The invention will be better understood with the aid of the following description of the preferred embodiments of the tool and of the battery of the invention, with
30 reference to the attached figure depicting them in section, but, for clarity, with no hatching.

The tool depicted in the figure in this instance is a hammer drill intended to strike a drill bit, also
35 driven in terms of rotation in support material, via a piston propelled in a cylinder, along an axis 1, under the action of an electric motor powered by a battery 3 arranged in an accommodating housing 4 formed in a leg 5, running roughly orthogonal to the axis 1 and

connected to the casing 2.

Also connected to the casing is an elbowed operating handle 6, with a leg portion 7 roughly parallel to the leg housing the battery 5 and a portion 8, for connection to the accommodating leg 5, running roughly parallel to the axis 1.

Housed in a housing 13 in the connecting portion of the handle 8 is a mechanical and electrical locking rod 9 running roughly parallel to the axis 1. In its continuation, on the side facing towards the battery housing 4, the rod 9 bears a locking finger 10.

The locking rod 9 also bears, laterally, an actuating trigger 11 projecting from the handle 6 through an aperture 14, on the inside 12, between the two portions 7, 8 and a return finger 15, running parallel to the rod 9, onto which there is slipped a return spring 16 bearing against the end wall 17 of the housing 13 and against a shoulder 18 formed by the finger 15. The locking finger 10 is shaped to exhibit a passage ramp 19 inclined towards the axis 1 from the rear 20 towards the front 21 of the tool, for the passage of the battery 3 as it slides into its housing 4.

In the rest position, which is the locked position, the locking finger 10 is returned by the spring 16 projecting into the battery housing 4. The rod 9 is moved into a position of retraction of the finger 10 against the action of the spring 16. In the battery accommodating leg 5, on the anterior side which is the opposite end to the operating handle 6, and therefore to the rod and to the locking finger, and near the casing 2, there is fixed, via one end 23, an elastic leaf 22, bearing a boss 24 at its free end forming a retaining finger facing towards the battery accommodating housing 4. The leaf 22 runs roughly orthogonally to the axis 1, but its free portion is,

however, inclined backwards so as to be able to pivot about its fixed end 23 and so that the retaining finger 24 can move roughly parallel to the axis 1, between a rest position, which is a locked position, in which it projects into the battery housing 4, and a retracted position, in its tool housing 38, against the elasticity of the leaf.

As far as the battery 3 is concerned, this battery being of roughly parallelepipedal overall shape, near its entry end face 25, it has, on its two opposed lateral sides 26, 27, two passage ramps 28, 29 for respectively negotiating the mechanical retaining finger 24 and the mechanical and electrical locking finger 10. A slight recess or hollow 30 is formed slightly beyond the ramp 28, exhibiting a ramp 31 inclined in the opposite direction to the ramp 28 to form, on the one hand, a boss 32 for the mechanical retention of the battery and, on the other hand, a housing 30 for accommodating the retaining finger 24 in the rest position. Here, the housing 30 is delimited not only by the ramp 31 but by another ramp 33 inclined in the opposite direction and situated at a distance away from the entry face 25 that is at least equal to the length of the leaf 22 considered in the direction in which the battery is introduced. Closer to its rear end face 34, on the side 27 of the battery, there is a locking catch 35 comprising an undercut internal shoulder 36, facing away from the entry face 25, and in this instance a ramp 37 inclined like the passage ramp 19 of the locking finger 10.

The fitting and removal of the battery 3 in the tool will now be explained.

Offering the battery 3 up via its entry face 25, it is introduced into the housing 4. It is pushed thereinto in the direction of the arrow 39, roughly orthogonal to the axis 1. The ramp 29, collaborating with the ramp 19

of the locking finger 10, retracts it into its housing 13, against the action of the spring 16. The battery continues to be pushed, the locking finger 10 sliding along the side 27 of the battery until the ramp 28, 5 collaborating with the retaining finger 24, retracts it in its turn into its tool housing 38 against the elasticity of the leaf 22, then until the retaining finger 24, having passed the boss 32, and through elastic relaxation of the leaf 22, returns to the 10 battery housing 30.

In this position, the battery is not yet electrically connected, but is mechanically retained in the tool in that, in order to extract it, it would be necessary to 15 pull on it to overcome the friction force needed for the boss 32 to move past the retaining finger 24.

It will be noted that, because of the height or extent of the battery housing 30, the battery can still move 20 to some extent, without the electrical connection ever being made inadvertently.

By continuing to push the battery 3 into its housing 4, it can be truly clipped in, that is to say mechanically 25 and electrically locked, when the retaining catch 35 comes opposite the retaining finger 10 which, under the action of the spring 16, is returned by sliding into the catch.

30 Conversely, to remove the battery 3 from its housing 4, the trigger 11 is actuated against the action of the spring 16 to disengage the finger 10 from the catch 35 then the battery is pulled to electrically disconnect the electrical components of the tool. It still, 35 however, remains mechanically secured to the tool, as long as the boss 32 has not been moved past the retaining finger 24. It is only by forcing this boss past the finger 24 and overcoming the corresponding friction forces that the battery can be fully removed

from the tool.
